(54) Title: **EXPRESSION SYSTEM**

(57) Abstract: The present invention provides a recombinant polynucleotide, the polynucleotide comprising a first and a second sequence, the first sequence encoding a signal peptide comprising a TAT signal and a Sec avoidance signal and the second sequence encoding a heterologous protein. The sequence of the signal peptide is M - X₁ - K/R - X₂ - K/R - X₃ - RR - X₄ - K/R - A in which X₁ is a sequence of 0 to 10 amino acids, X₂ is a sequence of 0 to 3 amino acids, X₃ is a sequence of 0 to 10 amino acids and X₄ is a sequence of 15 to 24 amino acids in which at least 75 % up to about 90 % of the residues are hydrophobic.

EXPRESSION SYSTEM

The present invention relates to a modified expression system for the transport and secretion of polypeptides. More specifically it relates to expression of proteins which readily fold in the cytoplasm.

5 BACKGROUND OF THE INVENTION

There is increasing interest in expression systems which enable bacterial production of recombinant proteins. In particular there is a need for systems which provide for high yield of recombinant proteins in culture supernatants particularly for agricultural and industrial uses. Recently, secretion of high yields of recombinant protein have been
10 obtained using *Brevibacillus*.

In bacteria, following expression of a protein, transmembrane translocation of the protein can proceed by a number of routes depending on the nature of both the targeting signal and the substrate. In general, most proteins destined for export are synthesised with N-terminal extensions, called signal peptides. Signal peptides
15 consist of short stretches of amino acids which, after protein delivery to the subcellular fraction, are removed. In bacteria two secretion pathways have been identified. The best characterised system is the Sec system for the general secretion of proteins. In this transport system, proteins are threaded through the membrane and correct folding occurs after transport.

20 The second system recently identified by Berks (1996) is the TAT system (for twin-arginine transfer peptide-dependent protein translocase). This system is so-called because the signal peptide generally contains the distinctive (S/T)RRXFLK motif. Proteins transported by this system are folded prior to translocation. Therefore, proteins of this type are toxic to bacteria if attempts are made to transport them
25 through the membrane with a Sec secretion signal, significantly limiting the production and recovery of the enzyme in these systems.

In general, cytoplasmic proteins readily fold in the cytoplasm of heterologous hosts. Therefore it would be predicted that this group of proteins may not be readily secreted by the Sec system. β -galactosidase is a classic example of this. This particular enzyme
30 from *E. coli* is a large protein with 120 kDa subunits and known to not pass through the cytoplasmic membrane when attached to a Sec-type secretion peptide (Manoil &

Beckwith, 1985; Bassford et al., 1979). An alternative system is required to facilitate recovery of proteins that readily fold in the cytoplasm.

One example of recombinant proteins which are required in high yield are enzymes which can be used to degrade organic pollutants.

- 5 Microorganisms are involved in the degradation of many organic compounds and are the principal agents for the biodegradation and recycling of organic matter. The degradation of organic compounds by microorganisms is primarily due to the action of various enzymes produced by the microorganism. The role of these enzymes in degrading organic pollutants has been investigated and a number of enzymes derived
10 from microorganisms have been identified that may be useful in assisting in bioremediation and the clean up of environmental pollutants and toxic compounds such as organophosphate pesticides.

- Residues of organophosphate insecticides are undesirable contaminants of the environment and a range of commodities. Areas of particular sensitivity include
15 contamination of soil, irrigation tailwater that is re-cycled, used by irrigators downstream or simply allowed to run off-farm, and residues above permissible levels in meat and horticultural exports. Poisoning with organophosphates presents a problem for agricultural workers that are exposed to these chemicals, as well as military personnel exposed to organophosphates used in chemical warfare.
20 Furthermore, the stockpiling of organophosphorus nerve agents has resulted in the need to detoxify these stocks. Bioremediation strategies are therefore required for eliminating or reducing these organophosphate residues and/or stockpiles.

- One proposed strategy involves the use of enzymes capable of immobilising or degrading the organophosphate residues. Such enzymes may be employed, for
25 example, in bioreactors through which contaminated water could be passed, or in washing solutions after post-harvest disinfestation of fruit, vegetables or animal products to reduce residue levels and withholding times. Suitable enzymes for degrading organophosphate residues include OP hydrolases from bacteria (Mulbry, 1992; Mulbry and Kearney, 1991; Cheng et al., 1999; US 5,484,728; US 5,589,386; Horne
30 et al., 2002; PCT/AU02/00594), vertebrates (Wang *et al.*, 1993; 1998; Gan *et al.*, 1991; Broomfield *et al.*, 1999) and OP resistant insects (PCT/AU95/00016 and PCT/AU96/00746).

The most thoroughly studied OP degrading enzyme is bacterial organophosphate dehydrolase (OPD), which is encoded by identical genes on dissimilar plasmids in both *Flavobacterium* sp. ATCC 27551 and *Brevundimonas diminuta* MG (Harper *et al.*, 1988; Mulbry and Karns, 1989). OPD is a homodimeric protein that is capable of hydrolysing a wide range of phosphate triesters (both oxon and thion OPs) with impressive kinetics (Dumas *et al.*, 1989a, b). Its reaction mechanism directly or indirectly involves metal ions, preferably Zn^{++} . OPD has no detectable activity with phosphate monoesters or diesters (Dumas *et al.*, 1989a, b; 1990).

OPD homologues (phosphotriesterase homology proteins, or PHPs) have been identified in the genomes of *Escherichia coli* (ePHP), *Mycobacterium tuberculosis* (mtPHP) and *Mycoplasma pneumoniae* (mpPHP), although only ePHP has been tested for phosphotriesterase activity (Scanlan and Reid, 1995; Buchbinder *et al.*, 1998). OPD homologues have also been identified in vertebrates (Davies *et al.*, 1997), although their function in these organisms is unknown.

OPD/OpdA have been identified as important enzymes that may assist in the bioremediation and clean up of environmental organophosphorus pollutants. Microorganisms such as bacteria should provide an important production tool for OPD/OpdA and various systems have been employed to increase the production and output of this enzyme. However expression systems are not available to provide sufficient quantities of this enzyme to meet the growing demand.

WO 02/22667 claims methods of producing polypeptides using the signal sequences from PhoD or LipA. This reference, however, provides no examples of production of polypeptides using a LipA signal sequence.

The present inventors have developed a novel expression system comprising a modified signal peptide which includes a Sec avoidance signal. It was found that this Sec avoidance signal was of critical importance for the production of polypeptides. This expression system has enabled the production of OpdA and other cytoplasmic proteins in high yields from *Brevibacillus*.

SUMMARY OF THE INVENTION

In a first aspect the present invention provides a recombinant polynucleotide, the polynucleotide comprising a first and a second sequence, the first sequence encoding a

signal peptide comprising a TAT signal and a Sec avoidance signal and the second sequence encoding a heterologous protein, wherein the sequence of the signal peptide is

5 in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

10 In a second aspect the present invention provides a signal peptide, the signal peptide having the sequence

in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

15 X_3 is a sequence of 0 to 10 amino acids; and

X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

In a third aspect the present invention provides a method of producing a heterologous polypeptide from a host cell comprising a TAT translocation system, the method
20 comprising:

(i) transforming the host cell with a DNA sequence encoding the heterologous polypeptide and a signal peptide wherein the signal peptide comprises a TAT signal and a Sec avoidance signal wherein the sequence of the signal peptide is

25 in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

- 5 (ii) culturing the host cell under conditions which allow expression of the heterologous polypeptide; and
- (iii) recovering the heterologous polypeptide secreted from the host cell via the TAT translocation system.

10 Preferably, the host cell is *Bacillus* sp. in particular a strain that produces little or no exoproteases such that degradation of the expressed protein is minimised. More preferably, the host cell is *Bacillus choshinensis*, *Bacillus brevis*, *Bacillus subtilis*, *Bacillus licheniformis*, or *Bacillus megaterium*. It is most preferred that the host cell is *Brevibacillus* sp, particularly *Bacillus choshinensis*. It is further preferred that the host cell is as described in US 4,946,789.

15 In a further preferred embodiment the heterologous polypeptide is a polypeptide which readily folds in the cytoplasm. In particular embodiments the polypeptide is OpdA.

In a fourth aspect, the present invention provides a substantially purified polypeptide produced according to the method of the first aspect.

20 DETAILED DESCRIPTION OF THE INVENTION

As discussed above the present inventors have developed a novel expression system comprising a modified signal peptide which includes a Sec avoidance signal. It was found that this Sec avoidance signal was of critical importance for the production of polypeptides. This expression system has enabled the production of OpdA and other
25 cytoplasmic proteins in high yields from *Brevibacillus*.

Accordingly, in a first aspect the present invention provides a recombinant polynucleotide, the polynucleotide comprising a first and a second sequence, the first sequence encoding a signal peptide comprising a TAT signal and a Sec avoidance

signal and the second sequence encoding a heterologous protein, wherein the sequence of the signal peptide is

in which X_1 is a sequence of 0 to 10 amino acids;

5 X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

10 In a second aspect the present invention provides a signal peptide, the signal peptide having the sequence

in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

15 X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

In a third aspect the present invention provides a method of producing a heterologous polypeptide from a host cell comprising a TAT translocation system, the method comprising:

20 (i) transforming the host cell with a DNA sequence encoding the heterologous polypeptide and a signal peptide wherein the signal peptide comprises a TAT signal and a Sec avoidance signal wherein the sequence of the signal peptide is

in which X_1 is a sequence of 0 to 10 amino acids;

25 X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

- 5 (ii) culturing the host cell under conditions which allow expression of the heterologous polypeptide; and
- (iii) recovering the heterologous polypeptide secreted from the host cell via the TAT translocation system.

10 Preferably, the host cell is *Bacillus sp.* in particular a strain that produces little or no exoproteases such that degradation of the expressed protein is minimised. More preferably, the host cell is *Bacillus choshinensis*, *Bacillus brevis*, *Bacillus subtilis*, *Bacillus licheniformis*, or *Bacillus megaterium*. It is most preferred that the host cell is *Brevibacillus sp.*, particularly *Bacillus choshinensis*. It is further preferred that the host cell is as described in US 4,946,789.

15 In a further preferred embodiment the heterologous polypeptide is a polypeptide which readily folds in the cytoplasm. In particular embodiments the polypeptide is OpdA.

In a fourth aspect, the present invention provides a substantially purified polypeptide produced according to the method of the first aspect.

20 In a preferred embodiment of the present invention X_1 is a sequence of 0 to 5 amino acids, and is preferably 0. It is preferred that X_2 is a sequence of 0 or 1 amino acid, preferably 0. It is preferred that X_3 is a sequence of 0 to 5 amino acids, preferably 0.

It is preferred that X_4 is a sequence of at least 20 amino acids of which at least 18 are hydrophobic amino acids. It is preferred X_4 is 23 amino acids.

25 In order to avoid any doubt as used herein the term "hydrophobic amino acids" means an amino acid selected from the group consisting of isoleucine, leucine, alanine, valine, glycine, phenylalanine and proline.

In a further preferred embodiment the sequence of the signal peptide is MKKRRVNSVLLLLLLASALALTVPMAKA (SEQ ID No:1).

While it is believed that the concept of signal sequences including a TAT signal are well known for the sake of clarity a number of such sequences are set out in Table 1.

Table 1 – A list of TAT sequences cited in Berks (1996). The signature "twin arginine" motif is in bold type.

As will be understood by those skilled in this area the method of the present invention is suitable for expression of a number of cytoplasmic proteins, including but not limited to, lipases, proteases, esterases and enzymes involved in carbohydrate metabolism.

As is well known in the art signal peptidases remove signal peptides from secretory proteins. Signal peptidases such as signal peptidase I (SPase I) cleave the signal

peptide at specific sites such as cleaving between contiguous alanine residues. In the present invention the C-terminal residue of the signal peptide is alanine. Accordingly, this signal peptide is adapted for use with a polypeptide which includes an alanine residue at the N-terminal of the mature protein.

- 5 In a fourth aspect, the present invention provides a substantially purified polypeptide produced according to the method of the first aspect.

In another preferred embodiment the polynucleotide encoding the mature polypeptide has a sequence selected from:

10 (i) a sequence of nucleotides shown in SEQ ID NO:29 from nucleotide 85 to 1155;

(ii) a sequence that hybridises to SEQ ID NO:29 from nucleotide 85 to 1155 under conditions of high stringency; and

(iii) a sequence which is greater than 90% identical to SEQ ID NO:29 from nucleotide 85 to 1155.

- 15 Preferably the mature heterologous polypeptide expressed by the method of the third aspect comprises the sequence provided in SEQ ID No:30 from residue 29 to 384; or a polypeptide which is greater than 90% identical to the sequence provided in SEQ ID No:30. More preferably, the polypeptide is at least 95% identical to the sequence provided in SEQ ID No:30, even more preferably at least 97% identical, and even more
20 preferably at least 99% identical to the sequence provided in SEQ ID No:30.

The present invention also provides a suitable vector for the replication and/or expression of the polynucleotide. The vectors may be, for example, a plasmid or phage vector provided with an origin of replication, and preferably a promoter for the expression of the polynucleotide and optionally a regulator of the promoter. The
25 vector may contain one or more selectable markers, for example an ampicillin resistance gene in the case of a bacterial plasmid. The vector may be used *in vitro*, for example to transfect or transform a host cell.

In a further aspect, the present invention relates to the transformed host cell of the third aspect.

In a preferred embodiment the host cell is a *Brevibacillus sp.*, preferably *Bacillus choshinensis*. Preferably, the host cell produces little or no exoproteases such that degradation of the expressed protein is minimised. It is further preferred that the host cell is as described in US 4,946,789. Such cells can be used for the production of
5 commercially useful quantities of the encoded polypeptide.

In yet another aspect, the present invention provides a fusion protein comprising a polypeptide according to the first aspect fused to at least one other polypeptide sequence.

In a preferred embodiment of this aspect, the at least one other polypeptide is selected
10 from the group consisting of: a polypeptide that enhances the stability of the polypeptide of the first or the second aspect, and a polypeptide that assists in the purification of the fusion protein.

In another aspect, the present invention provides a polynucleotide encoding the fusion protein.

15 The present invention also provides a composition for hydrolysing an organophosphate molecule, the composition comprising a polypeptide produced by the method of the third aspect of the present invention and one or more acceptable carriers.

In a still further aspect, the present invention provides a composition for hydrolysing
20 an organophosphate molecule, the composition comprising the host cell of the present invention and one or more acceptable carriers.

It will be appreciated that in preferred embodiments the polypeptide can be used to hydrolyse organophosphates in a sample. For instance, after a crop has been sprayed with an organophosphate pesticide, the organophosphate residue can be hydrolysed
25 from seeds, fruits and vegetables before human consumption. Similarly, organophosphate contaminated soil or water can be treated with a polypeptide of the second aspect of the present invention.

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art (e.g. in cell
30 culture, molecular genetics, nucleic acid chemistry, hybridisation techniques and biochemistry). Standard techniques are used for molecular, genetic and biochemical

methods (see generally, Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y. and Ausubel *et al.*, Short Protocols in Molecular Biology (1999) 4th Ed, John Wiley & Sons, Inc. - and the full version entitled Current Protocols in Molecular Biology, which are
5 incorporated herein by reference) and chemical methods.

Organophosphates are synthetic organophosphorus esters and related compounds such as phosphoramidates. They have the general formula $(RR'X)P=O$ or $(RR'X)P=S$, where R and R' are short-chain groups. For insecticidal organophosphates X is a good leaving group, which is a requirement for the irreversible inhibition of
10 acetylcholinesterase. The polypeptides of the present invention hydrolyse the phosphoester bonds of organophosphates.

Although well known for their use as pesticides, organophosphates have also been used as nerve gases against mammals. Accordingly, it is envisaged that the polypeptide of the present invention will also be useful for hydrolysis of
15 organophosphates which are not pesticides.

By "substantially purified" we mean a polypeptide that has been separated from the lipids, nucleic acids, other polypeptides, and other contaminating molecules with which it is associated in its native state.

The % identity of a polypeptide is determined by FASTA (Pearson and Lipman, 1988)
20 analysis (GCG program) using the default settings and a query sequence of at least 50 amino acids in length, and whereby the FASTA analysis aligns the two sequences over a region of at least 50 amino acids. More preferably, the FASTA analysis aligns the two sequences over a region of 100 amino acids.

OPDA activity as used herein refers to the ability of the enzyme to hydrolyse a
25 organophosphate molecule. OPDA activity may be determined by, for example, assaying culture supernatant containing secreted OPDA for activity against an organophosphate molecule. The organophosphate molecule may be selected from the group consisting of: coumaphos, coroxon, paraoxon, parathion, parathion-methyl, phosmet, fenthion, diazinon, chlorpyrifos, and dMUP. More preferably, the
30 organophosphate is phosmet or fenthion.

OPDA activity, such as activity against coumaphos, in for example, supernatant, may be compared to that in the cell fraction, or to the supernatant fraction obtained from a cell expressing a control, such as an unmodified OPDA.

Polynucleotides of the invention comprise nucleic acid sequences encoding the polypeptides of the invention. Polynucleotides of the invention may comprise DNA or RNA. They may also be polynucleotides which include within them synthetic or modified nucleotides. A number of different types of modification to oligonucleotides are known in the art. These include methylphosphonate and phosphorothioate backbones, addition of acridine or polylysine chains at the 3' and/or 5' ends of the molecule. For the purposes of the present invention, it is to be understood that the polynucleotides described herein may be modified by any method available in the art. Such modifications may be carried out in order to enhance the *in vivo* activity or life span of polynucleotides of the invention.

It will be understood by a skilled person that numerous different polynucleotides can encode the same polypeptide as a result of the degeneracy of the genetic code.

Polynucleotides of the invention can be incorporated into a recombinant replicable vector. The vector may be used to replicate the nucleic acid in a compatible host cell. Thus, in a further embodiment, the invention provides a method of making polynucleotides of the invention by introducing a polynucleotide of the invention into a replicable vector, introducing the vector into a compatible host cell, and growing the host cell under conditions which bring about replication of the vector. The vector may be recovered from the host cell. Suitable host cells include bacteria such as *Brevibacillus*.

Preferably, a polynucleotide of the invention in a vector is operably linked to a regulatory sequence that is capable of providing for the expression of the coding sequence by the host cell, i.e. the vector is an expression vector. The term "operably linked" refers to a juxtaposition wherein the components described are in a relationship permitting them to function in their intended manner. A regulatory sequence "operably linked" to a coding sequence is ligated in such a way that expression of the coding sequence is achieved under conditions compatible with the control sequences.

Such vectors may be transformed or transfected into a suitable host cell as described above to provide for expression of a polypeptide of the invention. This process may comprise culturing a host cell transformed with an expression vector as described above under conditions to provide for expression by the vector of a coding sequence
5 encoding the polypeptides, and optionally recovering the expressed polypeptides.

The vectors may be, for example, plasmid vectors provided with an origin of replication, optionally a promoter for the expression of the said polynucleotide and optionally a regulator of the promoter. The vectors may contain one or more selectable marker genes, for example an ampicillin resistance gene in the case of a
10 bacterial plasmid. Vectors may be used *in vitro*, for example to transfect or transform a host cell.

Promoters/enhancers and other expression regulation signals may be selected to be compatible with the host cell for which the expression vector is designed. For example, prokaryotic promoters may be used, in particular those suitable for use in
15 *Brevibacillus* strains (such as *Bacillus brevis* and *Bacillus choshinensis*). A bacterial promoter may also have a second domain called an operator, that may overlap an adjacent RNA polymerase binding site at which RNA synthesis begins. The operator permits negative regulated (inducible) transcription, as a gene repressor protein may bind the operator and thereby inhibit transcription of a specific gene. Constitutive
20 expression may occur in the absence of negative regulatory elements, such as the operator. In addition, positive regulation may be achieved by a gene activator protein binding sequence, which, if present is usually proximal (5') to the RNA polymerase binding sequence. An example of a gene activator protein is the catabolite activator protein (CAP), which helps initiate transcription of the lac operon in *E. coli* (Raibaud
25 et al., Ann. Rev. Genet., 18: 173, 1984). In addition, synthetic promoters which do not occur in nature also function as bacterial promoters. For example, transcription activation sequences of one bacterial or bacteriophage promoter may be joined with the operon sequences of another bacterial or bacteriophage promoter, creating a synthetic hybrid promoter (U.S. Pat. No. 4,551,433). For example, the tac promoter is a
30 hybrid trp-lac promoter comprised of both trp promoter and lac operon sequences that is regulated by the lac repressor (Amann et al., Gene, 25: 167, 1983; de Boer et al., Proc. Natl. Acad. Sci. USA, 80: 21, 1983). Furthermore, a bacterial promoter can include naturally occurring promoters of non-bacterial origin that have the ability to bind bacterial RNA polymerase and initiate transcription. A naturally occurring promoter

of non-bacterial origin can also be coupled with a compatible RNA polymerase to produce high levels of expression of some genes in prokaryotes.

Phage promoters may also be used, for example lambda. These promoters are readily available in the art.

- 5 Oligonucleotides and/or polynucleotides of the present invention may selectively hybridise to the sequence set out in SEQ ID NO:29 under high stringency. As used herein, stringent conditions are those that (1) employ low ionic strength and high temperature for washing, for example, 0.015 M NaCl/0.0015 M sodium citrate/0.1% NaDodSO₄ at 50°C; (2) employ during hybridisation a denaturing agent such as
- 10 formamide, for example, 50% (vol/vol) formamide with 0.1% bovine serum albumin, 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 50 mM sodium phosphate buffer at pH 6.5 with 750 mM NaCl, 75 mM sodium citrate at 42°C; or (3) employ 50% formamide, 5 x SSC (0.75 M NaCl, 0.075 M sodium citrate), 50 mM sodium phosphate (pH 6.8), 0.1% sodium pyrophosphate, 5 x Denhardt's solution, sonicated salmon sperm DNA
- 15 (50 g/ml), 0.1% SDS and 10% dextran sulfate at 42°C in 0.2 x SSC and 0.1% SDS.

Vectors and polynucleotides of the invention may be introduced into host cells for the purpose of replicating the vectors/polynucleotides and/or expressing the polypeptides of the invention encoded by the polynucleotides of the invention. Suitable host cells include prokaryotes such as *Brevibacillus*.

- 20 Suitable host cells to transform include any cell that can be transformed with a polynucleotide of the present invention. Host cells can be either untransformed cells or cells that are already transformed with at least one nucleic acid molecule (e.g., nucleic acid molecules encoding one or more proteins of the present invention). Host cells of the present invention can be capable of producing such proteins after being
- 25 transformed with at least one nucleic acid molecule of the present invention. Host cells of the present invention can be any cell capable of producing at least one protein of the present invention.

- Vectors/polynucleotides of the invention may be introduced into suitable host cells using a variety of techniques known in the art, such as transfection, transformation
- 30 and electroporation. More preferred host cells are selected from the *Brevibacillus* cluster comprising the following species, namely, *Bacillus brevis*, *Bacillus agri*, *Bacillus centrosporus*, *Bacillus choshinensis*, *Bacillus parabrevis*, *Bacillus reuszeri*, *Bacillus*

formosus, *Bacillus borstelensis*, *Bacillus laterosporus*, and *Bacillus thermoruber*. Even more preferred host cells are *Bacillus brevis* and *Bacillus choshinensis*.

Host cells of the present invention can be cultured in conventional fermentation bioreactors. The host cells can be cultured by any fermentation process which
5 includes, but is not limited to, batch, fed-batch, cell recycle, and continuous fermentation. Preferably, host cells of the present invention are grown by batch or fed-batch fermentation processes.

Another embodiment of the present invention includes a recombinant cell comprising a host cell transformed with one or more recombinant molecules of the present
10 invention. Transformation of a nucleic acid molecule into a cell can be accomplished by any method by which a nucleic acid molecule can be inserted into the cell.

Host cells comprising polynucleotides of the invention may be used to express polypeptides of the invention. Host cells may be cultured under suitable conditions which allow expression of the polypeptide produced according to the invention.
15 Expression of the polypeptides of the invention may be constitutive such that they are continually produced, or inducible, requiring a stimulus to initiate expression. In the case of inducible expression, protein production can be initiated when required by, for example, addition of an inducer substance to the culture medium, for example dexamethasone or IPTG.

20 Polypeptides of the invention can be collected from the supernatant of cultures of host cells expressing OpdA of the invention.

Purification of polypeptides may optionally be performed using well known techniques such as affinity chromatography, including immunoaffinity chromatography, ion-exchange chromatography and the like, or affinity
25 chromatography systems based on fusion protein sequences such as those known in the art.

Recombinant DNA technologies can be used to improve expression of polypeptide molecules by manipulating, for example, the number of copies of the polynucleotide within a host cell, the efficiency with which those polynucleotides molecules are
30 transcribed and the efficiency with which the resultant transcripts are translated. Recombinant techniques useful for increasing the expression of polynucleotide

molecules of the present invention include, but are not limited to, operatively linking polynucleotide molecules to high-copy number plasmids, addition of vector stability sequences to plasmids, substitutions or modifications of transcription control signals (e.g., promoters, operators, enhancers), substitutions or modifications of translational control signals (e.g., ribosome binding sites, Shine-Dalgarno sequences), modification
5 of polynucleotide molecules of the present invention to correspond to the codon usage of the host cell, and the deletion of sequences that destabilize transcripts. The activity of an expressed recombinant protein of the present invention may be improved by fragmenting, modifying, or derivatizing polynucleotide molecules encoding such a
10 protein.

All publications mentioned in the above specification are herein incorporated by reference. Various modifications and variations of the described methods and system of the invention will be apparent to those skilled in the art without departing from the scope and spirit of the invention. Although the invention has been described in
15 connection with specific preferred embodiments, it should be understood that the invention as claimed should not be unduly limited to such specific embodiments. Indeed, various modifications of the described modes for carrying out the invention which are apparent to those skilled in molecular biology or related fields are intended to be within the scope of the invention.

20 Any discussion of documents, acts, materials, devices, articles or the like which has been included in the present specification is solely for the purpose of providing a context for the present invention. It is not to be taken as an admission that any or all of these matters form part of the prior art base or were common general knowledge in Australia in the field relevant to the present invention

25 Throughout this specification the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps.

In order that the nature of the present invention may be more clearly understood
30 preferred forms thereof will now be described by reference to the following non-limiting Examples.

EXAMPLES

Expression of OpdA

The amino acid sequence of OpdA including the native signal peptide is shown in SEQ ID NO. 30. In this sequence the signal peptide is residues 1 to 28 and the sequence is set out below. Examination of this sequence shows that it possesses the distinctive twin arginine motif of the TAT system which implies that OpdA is folded prior to secretion and cleavage of the signal peptide. Therefore it is unlikely that OpdA can be secreted through the Sec system.

MQTRRDALKSAAAITLLGGLAGCASMAR (SEQ ID No:31)

(The signal peptide of OpdA with the TAT motif underlined.)

In an effort to obtain higher yields of OpdA, expression of the protein was attempted using a Brevibacillus expression system developed by Higeta Shoya Co. Ltd. In using this system the native signal peptide was deleted and replaced with the following sequence:

MKKRRVNSVLLLLLLASALALTVPMAFA | AGS (SEQ ID No:32)

(| indicates SpaseI cleavage site)

Attempts using this expression system were unsuccessful.

In an effort to understand this failure it was noted that while the modified signal peptide possessed the "twin arginine" motif of the TAT system it lacked a positively charged residue near the cleavage site which Tjalsma *et al.* (2000) had found acts as a Sec avoidance signal in *Bacillus subtilis*. In an effort to determine whether expression could be achieved by incorporation of a Sec avoidance signal, the signal peptide was modified to include a positively-charged residue and a "Bacillus" type signal peptidase (SPaseI) cleavage site.

Two complementary oligos (NCMO25', 5'GTTTCAGCCCATGGCTAAAGCTGCAGAGCACGGATCCGATC (SEQ ID No:33) and NCMO23', 5'GATCGGATCCGTGCTCTGCAGCTTTAGCCATGGGCTGAAC (SEQ ID No:34)) containing an NcoI site and one end (underlined) and a BamHI site at

the other end (bold-type) were designed to alter the signal peptide to that shown below.

(a) MKKRRVNSVLLLLLLASALALTVAPMAFA|AGS (SEQ ID No:35)

(b) MKKRRVNSVLLLLLLASALALTVAPMAKA|AEH (SEQ ID No:36)

- 5 The amino acid sequence of the original signal peptide in pNCMO2 (a) and the altered signal peptide in pNC(mod) (b).

The two oligos were dissolved in TE buffer to 44 nmol/ml. Ten microlitres of each were incubated for 10 minutes at 95°C and then cooled slowly to room temperature. This would melt the two complimentary bands together. This was then digested with
10 *NcoI* and *BamHI*. The plasmid pNCMO2 was digested with *NcoI* and *BamHI* and extracted from a 1% agarose gel using the QIAquick PCR purification kit (QIAGEN). The digested pNCMO2 and digested oligos were ligated overnight and transformed the following day into *E. coli* DH10β. All transformations in *E. coli* were performed according to the revised Hanahan method (Sambrook *et al.*, 1989). Transformants
15 were selected on LB agar plates (10 g/l tryptone, 5 g/l Yeast Extract, 2.5 g/l NaCl) containing 100 µg/ml ampicillin. One transformant containing an altered signal peptide (as determined by DNA sequencing) was selected and designated pNC(mod).

Construction of pNC(mod)-*opdA*

The plasmid pNC(mod) was digested with *BamHI* and *EcoRI* and excised from a 1%
20 agarose gel using the QIAquick PCR purification kit (QIAGEN). The plasmid pGAfull was digested with *BamHI* and *EcoRI* and the 1 kb *opdA* containing fragment was excised from a 1% agarose gel using the QIAquick PCR purification kit and ligated overnight with the extracted pNC(mod) fragment. The ligation mixture was transformed into *E. coli* CC118 (*araD139*, Δ (*ara*, *leu*)7697, Δ *lacX74*, *phoA*Δ20, *galE*,
25 *galK*, *thi*, *rpsE*, *rpoB*, *argE*_{am1}, *recA1*; Manoil & Beckwith, 1985) and transformants selected on LB plates containing ampicillin (100 µg/ml). The *opdA* expression in pNC(mod)-*opdA* is run from a *lacZ* promoter and there is leaky expression from *lac* promoters in some *E. coli* strains. However, no expression from *lac* promoters occurs in *E. coli* CC118 due to deletion of the *lac* operon. Transformation into *E. coli* DH10β
30 resulted in point mutations in *opdA*, resulting in the production of a non-functional

protein. This is probably due to an inability of the signal peptide to target the TAT secretion system and avoid the Sec system in *E. coli*.

Expression of *opdA* in *Brevibacillus choshinensis*

The plasmid pNC(mod)-*opdA* was transformed into *Brevibacillus choshinensis*.

- 5 HPD31 (Takagi *et al.*, 1989) using the Tris-PEG method of Udaka & Yamagata (1993) and transformants selected on BTY medium (glucose, 1.0%; tryptone, 2.0%; Yeast Extract, 0.5%; $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, 0.001%; $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$, 0.001%; $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$, 0.001%) with 20 mM MgCl_2 and 50 $\mu\text{g}/\text{ml}$ neomycin at 28°C. One transformant was picked and grown up for further analysis. The plasmid contained in this transformant was
- 10 extracted and examined and shown to be pNC(mod)-*opdA*. *B. choshinensis* pNC(mod)-*opdA* was grown to mid-log phase and induced with 1 mM IPTG at 28°C for 24 hours in BTY medium with 50 $\mu\text{g}/\text{ml}$ neomycin. The culture supernatant and cells were separated by centrifugation (7000 *g*, 10 minutes). The cell pellet was resuspended in 2 ml 50 mM Tris-HCl pH7.5 and sonicated.

15 Tris-PEG method of transformation

B. choshinensis was streaked onto BTY medium and grown at 37°C for 2 days. A loopful of growth was then used to inoculate 5 ml of BTY medium and grown overnight at 37°C. The overnight culture was diluted 100-fold in 5 ml of the same medium and incubated at 37°C for 5 hours. The cells were then pelleted by

- 20 centrifugation (4000 *g*, 5 minutes) and washed with 5 ml of 50 mM Tris-HCl pH7.5. The pellet was finally resuspended in 5 ml of 50 mM Tris-HCl pH8.5 and incubated for 30 minutes at 37°C. After this incubation the cell pellet was washed with 1 ml of MTP. MTP was prepared as follows:

0.1 M Sodium Maleate pH6.5	20 ml
Phosphate Buffer(7% w/v K_2HPO_4 / 2.5% w/v KH_2PO_4)	10 ml
H_2O	18 ml

- 25 Autoclave and then add:

1 M MgCl_2 (filter-sterilised)	2 ml
BTY	50 ml

Plasmid DNA was added to the cell suspension, after which 1.5 ml of a PEG solution (40 g PEG8000, 20 ml 0.1 M Sodium maleate pH6.5 and H₂O to 100 ml) was added and the mixture incubated at room temperature for 2 minutes. MTP (5 ml) was added and mixed well. The cells were collected by centrifugation (4000 *g*, 10 minutes at room temperature). The cells were then resuspended in 1 ml of BTY with 20 mM MgCl₂ and incubated at 30°C for 2.5 hours with moderate shaking.

Checking for expression

Both the supernatant and the cell extracts were examined for coumaphos hydrolytic activity and SDS-PAGE. No coumaphos hydrolytic activity could be detected in *B. choshinensis* cells in the absence of pNC(mod)-opdA. The majority of the coumaphos hydrolytic activity was secreted into the culture supernatant (Table 2). The specific activity of the supernatant was 5.09 $\mu\text{mol}/\text{min}/\text{mg}$ protein), which is close to that of purified OpdA (8.0 $\mu\text{mol}/\text{min}/\text{mg}$ protein), suggesting that OpdA in the supernatant is relatively pure.

Table 2 – The percentage coumaphos hydrolytic activity in *B. choshinensis* with various plasmids.

Strain	Supernatant	Cells
<i>B. choshinensis</i> pNC(mod)-opdA	64.8 \pm 7.6	35.2 \pm 4.2
<i>B. choshinensis</i> pNC(mod)	nd ¹	nd

nd¹ = not detected

The signal peptide allows secretion of active cytoplasmic proteins

In general, cytoplasmic proteins readily fold in the cytoplasm of heterologous hosts. Therefore it would be predicted that this group of proteins may not be readily secreted by the Sec system. β -galactosidase is a classic example of this. This particular enzyme from *E. coli* is a large protein of 120 kDa and known to not pass through the cytoplasmic membrane when attached to a Sec-type secretion peptide (Manoil & Beckwith, 1985; Bassford *et al.*, 1979). Therefore, this protein was chosen to examine the secretion of active cytoplasmic proteins by this *Brevibacillus* system.

The *lacZ* gene was amplified by PCR using pEM32m as a template. The primers used were lac5c (5'CATGTCGACATGGATCCCGTCGTT) (SEQ ID No:37) and lac3b

- (5'CATGAATTCTTATTTTGAAGTGGTAA) (SEQ ID No:38) containing *SaI* and *EcoRI* sites, respectively. The PCR was performed using the *Pfu* Turbo DNA polymerase from Stratagene, according to the manufacturer's instructions. The 3 kb PCR product was purified using the QIAquick PCR purification kit and ligated with
- 5 pGEM T Easy (Promega) overnight. The ligation mixture was then transformed into *E. coli* DH10 β and transformants selected on LB plates containing ampicillin (100 μ g/ml), X-Gal (5-bromo-4-chloro-3-indolyl β -D galactoside, 40 μ g/ml) and IPTG (40 μ g/ml). It was noted that there were some intense blue colonies on the plates. One was examined and shown to contain the 3 kb PCR product encoding β -galactosidase.
- 10 This plasmid was called pGEMlac and demonstrates the presence of a functional β -galactosidase enzyme. When this insert was contained in the opposite orientation, no β -galactosidase activity was generated (Table 3).

Table 3 – The β -galactosidase activity in *E. coli* DH10 β cells with various constructs.

Strain	β -galactosidase activity (nmol/min/ μ g protein)
<i>E. coli</i> DH10 β pGEMlac2 ¹	0.0054 \pm 0.0009
<i>E. coli</i> DH10 β pGEMlac5 ²	11.001 \pm 0.007

¹*lacZ* is contained in the opposite orientation to *lac* promoter

- 15 ²*lacZ* is contained in the same orientation as the *lac* promoter

- The *SaI*-*EcoRI* fragment containing β -galactosidase was ligated with similarly-digested pNC(mod). The ligation mix was transformed into *E. coli* CC118 and transformants selected on LB plates containing ampicillin (100 μ g/ml). Several transformants were picked and examined for inserts. One was chosen and shown to
- 20 contain the 3 kb *SaI*-*EcoRI* fragment. This plasmid was designated pNC(mod)-lac. This plasmid was then transformed into *Brevibacillus* and transformants selected on BTY medium with 50 μ g/ml neomycin at 30°C. One colony was picked after two days growth and examined for the production of β -galactosidase when induced with IPTG. The culture was pelleted by centrifugation (7000g, 10 minutes) and the cell pellet
- 25 resuspended in 50 mM Tris-HCl pH7.5, after which it was sonicated. Both the cell extract and the culture supernatant were examined for β -galactosidase activity. The majority of the β -galactosidase activity was contained in the supernatant (Table 4). *Brevibacillus choshinensis* does not possess any intrinsic β -galactosidase activity.

Table 4 – The percentage β -galactosidase activity in *B. choshinensis* cells with various plasmids.

Strain	Supernatant	Cells
<i>B. choshinensis</i> pNC(mod)-lac	98.2±6.0	1.80±0.17
<i>B. choshinensis</i> pNC(mod)	nd ¹	nd

¹not detected

- This secretion system was tested on another cytoplasmic protein, that is also a phosphotriesterase. Horne *et al.* (2002b) identified the protein HocA from a *Pseudomonas monteilli* strain that is capable of hydrolysing organophosphates. This protein is a 20 kDa cytoplasmic protein unrelated in sequence and reaction mechanism to OpdA. The *hocA* gene was amplified by PCR using the upstream and downstream oligonucleotide primers, hoc5,
- 5'GTCTAAGGATCCATGAAAGAAGAACTAAAAACC, (SEQ ID No:39) and hoc3, 5'GTCTAAAAGCTTTTACCAGTTTAGCTTTAG, (SEQ ID No:40) with *Bam*HI and *Hind*III restriction sites (underlined), respectively, and the template pBSRK7(1) as a template. The PCR product was digested with *Bam*HI and *Hind*III and cloned into similarly-digested pK18. The ligation was transformed into *E. coli* DH10 β . One transformant was chosen and shown by sequence analysis to have a correct *hocA* gene. This clone was designated pKhoc2. The 501 bp *hocA*-containing *Bam*HI-*Hind*III fragment of pKhoc2 was then cloned into pNC(mod) and transformed into *E. coli* CC118. One clone was selected that possessed *hocA* and this clone was designated pNC(mod)-hoc. The plasmid pNC(mod)-hoc was transformed into *Brevibacillus choshinensis* with transformants selected on BTY medium with 50 μ g/ml neomycin at 30°C. One colony was picked after two days growth and grown in 50 ml BTY medium to mid-log phase and then induced with 1 mM IPTG at 28°C for 24 hours. The culture supernatant and cells were separated by centrifugation (7000g, 10 minutes). The cell pellet was resuspended in 50 mM Tris-HCl pH7.5 and sonicated. The coumaphos hydrolytic activity in the cell extract and in the culture supernatant was determined. Table 5 shows the relative amounts of activity. The majority of the protein was secreted in an active form into the culture supernatant.

Table 5 – The percentage coumaphos hydrolytic activity in *B. choshinensis* with various plasmids

Strain	Supernatant	Cells
<i>B. choshinensis</i> pNC(mod)	nd ¹	nd
<i>B. choshinensis</i> pNC(mod)-hoc	75.1±6.8	24.9±0.9

CLAIMS

1. A recombinant polynucleotide, the polynucleotide comprising a first and a second sequence, the first sequence encoding a signal peptide comprising a TAT signal and a Sec avoidance signal and the second sequence encoding a heterologous protein,
5 wherein the sequence of the signal peptide is

in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

- 10 X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

2. A recombinant polynucleotide according to claim 1 wherein X_1 is a sequence of 0 to 5 amino acids, and is preferably 0.

3. A recombinant polynucleotide according to claim 1 or 2 wherein X_2 is a
15 sequence of 0 or 1 amino acid, preferably 0.

4. A recombinant polynucleotide according to any one of claims 1 to 3 wherein X_3 is a sequence of 0 to 5 amino acids, preferably 0.

5. A recombinant polynucleotide according to any one of claims 1 to 4 wherein X_4 is a sequence of at least 20 amino acids of which at least 18 are hydrophobic amino
20 acids.

6. A recombinant polynucleotide according to any one of claims 1 to 5 wherein X_4 is 23 amino acids.

7. A recombinant polynucleotide according to any one of claims 1 to 6 wherein the sequence of the signal peptide is MKKRRVNSVLLLLLLASALALTVPMAKA
25 (SEQ ID NO: 1).

8. A signal peptide, the signal peptide having the sequence

in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

5 X_4 is a sequence of 15 to 24 amino acids in which at least 75% up to about 90% of the residues are hydrophobic.

9. A signal peptide according to claim 8 wherein X_1 is a sequence of 0 to 5 amino acids, and is preferably 0.

10 10. A signal peptide according to claim 8 or 9 wherein X_2 is a sequence of 0 or 1 amino acid, preferably 0.

11. A signal peptide according to any one of claims 8 to 10 wherein X_3 is a sequence of 0 to 5 amino acids, preferably 0.

12. A signal peptide according to any one of claims 8 to 11 wherein X_4 is a sequence of at least 20 amino acids of which at least 18 are hydrophobic amino acids.

15 13. A signal peptide according to any one of claims 8 to 12 wherein X_4 is 23 amino acids.

14. A signal peptide according to any one of claims 8 to 13 wherein the sequence of the signal peptide is MKKRRVNSVLLLLLLASALALTVPMAKA (SEQ ID NO 1).

20 15. A method of producing a heterologous polypeptide from a host cell comprising a TAT translocation system, the method comprising:

(i) transforming the host cell with a DNA sequence encoding the heterologous polypeptide and a signal peptide wherein the signal peptide comprises a TAT signal and a Sec avoidance signal wherein the sequence of the signal peptide is

25 in which X_1 is a sequence of 0 to 10 amino acids;

X_2 is a sequence of 0 to 3 amino acids;

X_3 is a sequence of 0 to 10 amino acids; and

X_4 is a sequence of 15 to 24 amino acids, in which at least 75% up to about 90% of the residues are hydrophobic.

- 5 (ii) culturing the host cell under conditions which allow expression of the heterologous polypeptide; and
- (iii) recovering the heterologous polypeptide secreted from the host cell via the TAT translocation system.
16. A method according to claim 15 wherein X_1 is a sequence of 0 to 5 amino
10 acids, and is preferably 0.
17. A method according to claim 15 or 16 wherein X_2 is a sequence of 0 or 1 amino acid, preferably 0.
18. A method according to any one of claims 15 to 17 wherein X_3 is a sequence of 0 to 5 amino acids, preferably 0.
- 15 19. A method according to any one of claims 15 to 18 wherein X_4 is a sequence of at least 20 amino acids of which at least 18 are hydrophobic amino acids.
20. A method according to any one of claims 15 to 19 wherein X_4 is 23 amino acids.
21. A method according to any one of claims 15 to 20 wherein the sequence of the
20 signal peptide is MKKRRVVNSVLLLLLLASALALTVPMAKA (SEQ ID NO: 1).
22. A method according to any one of claims 15 to 21 wherein the host cell is *Bacillus sp.*
23. A method according to claim 22 wherein the host cell is selected from the group consisting of *Bacillus choshinensis*, *Bacillus brevis*, *Bacillus subtilis*, *Bacillus*
25 *licheniformis*, and *Bacillus megatorium*.
24. A method according to claim 22 wherein the host cell is *Bacillus choshinensis*.

25. A method according to any one of claims 15 to 24 wherein the heterologous polypeptide is a polypeptide which readily folds in the cytoplasm.

26. A method according to any one of claims 15 to 25 wherein the polynucleotide encoding the mature polypeptide has a sequence selected from:

5 (i) a sequence of nucleotides shown in SEQ ID NO:29 from nucleotide 85 to 1155;

(ii) a sequence that hybridises to SEQ ID NO:29 from nucleotide 85 to 1155 under conditions of high stringency;

10 (iii) a sequence which is greater than 90% identical to SEQ ID NO:29 from nucleotide 85 to 1155; and

(iv) a sequence that encodes the amino acid sequence provided in SEQ ID NO:30 from residue 29 to 384.

15 27. A method according to any one of claims 15 to 25 wherein the mature heterologous polypeptide comprises the sequence provided in SEQ ID NO:30 from residue 29 to 384; or a polypeptide which is greater than 90% identical to the sequence provided in SEQ ID NO:30.

28. A substantially purified polypeptide produced according to the method of any one of claims 15 to 27.

20 29. A vector comprising the recombinant polynucleotide according to any of claims 1 to 8.

30. A host cell comprising the recombinant polynucleotide according to any of claims 1 to 8.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/AU03/00951

A. CLASSIFICATION OF SUBJECT MATTER		
Int. Cl. ⁷ : C07K 14/345, C12N 15/70, According to International Patent Classification (IPC) or to both national classification and IPC		
B. FIELDS SEARCHED		
Minimum documentation searched (classification system followed by classification symbols)		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched		
Electronic data base consulted during the international search (name of data base and, where practicable, search terms used) STN: File CA, sequence search		
C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
P,X	Blaudeck, N. et al "Genetic Analysis of Pathway Specificity during Posttranslational Protein Translocation across the <i>Escherichia coli</i> Plasma Membrane" Journal of Bacteriology , May 2003, p2811-2819 See whole document	1-30
A	Pop, O. et al, "The Twin-arginine Signal Peptide of PhoD and the TatA _d /C _d Proteins of <i>Bacillus subtilis</i> Form an Autonomous Tat Translocation System" The Journal of Biological Chemistry " Vol 277, No 5, Issue of February 1, pp 3268-3273, Published 21 November 2001. See whole document	1-30
<input checked="" type="checkbox"/> Further documents are listed in the continuation of Box C <input type="checkbox"/> See patent family annex		
<p>* Special categories of cited documents:</p> <p>"A" document defining the general state of the art which is not considered to be of particular relevance</p> <p>"B" earlier application or patent but published on or after the international filing date</p> <p>"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)</p> <p>"O" document referring to an oral disclosure, use, exhibition or other means</p> <p>"P" document published prior to the international filing date but later than the priority date claimed</p> <p>"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention</p> <p>"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone</p> <p>"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art</p> <p>"&" document member of the same patent family</p>		
Date of the actual completion of the international search 20 October 2003		Date of mailing of the international search report 4 NOV 2003
Name and mailing address of the ISA/AU AUSTRALIAN PATENT OFFICE PO BOX 200, WODEN ACT 2606, AUSTRALIA E-mail address: pct@ipaaustralia.gov.au Facsimile No. (02) 6285 3929		Authorized officer  IAN DOWD Telephone No : (02) 6283 2273

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☒ FADED TEXT OR DRAWING
- ☐ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☒ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☐ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
